

1 FLAT RHEOLOGY DRILLING FLUID

2 BACKGROUND

3 In rotary drilling of subterranean wells numerous functions and characteristics are
4 expected of a drilling fluid. A drilling fluid should circulate throughout the well and
5 carry cuttings from beneath the bit, transport the cuttings up the annulus, and allow their
6 separation at the surface. At the same time, the drilling fluid is expected to cool and
7 clean the drill bit, reduce friction between the drill string and the sides of the hole, and
8 maintain stability in the borehole's uncased sections. The drilling fluid should also form a
9 thin, low permeability filter cake that seals openings in formations penetrated by the bit
10 and act to reduce the unwanted influx of formation fluids from permeable rocks.

11 Drilling fluids are typically classified according to their base material. In oil base
12 fluids, solid particles are suspended in oil, and water or brine may be emulsified with the
13 oil. The oil is typically the continuous phase. In water base fluids, solid particles are
14 suspended in water or brine, and oil may be emulsified in the water. The water is
15 typically the continuous phase. Pneumatic fluids are a third class of drilling fluids in
16 which a high velocity stream of air or natural gas removes drill cuttings.

17 Oil-based drilling fluids are generally used in the form of invert emulsion muds.
18 An invert emulsion mud consists of three-phases: an oleaginous phase, a non-oleaginous
19 phase and a finely divided particle phase. Also typically included are emulsifiers and
20 emulsifier systems, weighting agents, fluid loss additives, alkalinity regulators and the
21 like, for stabilizing the system as a whole and for establishing the desired performance
22 properties. Full particulars can be found, for example, in the Article by P. A. Boyd et al
23 entitled "New Base Oil Used in Low-Toxicity Oil Muds" in the Journal of Petroleum
24 Technology, 1985, 137 to 142 and in the Article by R. B. Bennet entitled "New Drilling
25 Fluid Technology-Mineral Oil Mud" in Journal of Petroleum Technology, 1984, 975 to
26 981 and the literature cited therein.

27 It is important that the driller of subterranean wells be able to control the
28 rheological properties of drilling fluids. In the oil and gas industry today it is desirable
29 that additives work both onshore and offshore and in fresh and salt-water environments.
30 In addition, as drilling operations impact on plant and animal life, drilling fluid additives

1 should have low toxicity levels and should be easy to handle and to use to minimize the
2 dangers of environmental pollution and harm to operators. Any drilling fluid additive
3 should also provide the desired results but at the same time the additive should not inhibit
4 the desired performance of other components of the drilling fluid. The development of
5 such additives will help the oil and gas industry to satisfy the long felt need for superior
6 drilling fluid additives which act to control the rheological properties of drilling fluids.

8 SUMMARY

9 The subject matter of the present disclosure is generally directed to a drilling
10 fluid formulated to include: an oleaginous fluid that forms the continuous phase; a non-
11 oleaginous fluid that forms the discontinuous phase, a primary emulsifier which is in
12 sufficient concentration to stabilize the invert emulsion; and a rheology modifier selected
13 to substantially achieve the result disclosed above. It is preferred that the rheology
14 modifier is a concentration sufficient to achieve the result described above and is selected
15 from poly-carboxylic fatty acids and poly-amides. In one preferred illustrative
16 embodiment, the poly-carboxylic fatty acid dimer poly-carboxylic C₁₂ to C₂₂ fatty acid,
17 trimer poly-carboxylic C₁₂ to C₂₂ fatty acid, tetramer poly-carboxylic C₁₂ to C₂₂ fatty acid,
18 mixtures of these acids as well as combinations and mixtures of these and similar
19 compounds that should be known to one of skill in the art. For another illustrative
20 embodiment, the rheology modifier is a poly-amide or mixtures polyamides formed from
21 the condensation reaction of C₁₂ to C₂₂ fatty acid and di- tri- tetra- and penta-
22 ethylenepolyamines and the resulting similar compounds that should be known to one of
23 skill in the art. As noted above, the oleaginous fluid utilized in the present illustrative
24 embodiment forms the continuous phase and is about 30% to about 100% by volume of
25 the drilling fluid and preferably is selected from diesel oil, mineral oil, synthetic oil,
26 esters, ethers, acetals, di-alkylcarbonates, olefins, as well as combinations and mixtures of
27 these and similar compounds that should be known to one of skill in the art. In another
28 illustrative embodiment, the non-oleaginous fluid composes the discontinuous phase and
29 is about 1% to about 70% by volume of said drilling fluid with preferred non-oleaginous
30 fluid being selected from fresh water, sea water, a brine containing organic or inorganic

1 dissolved salts, a liquid containing water-miscible organic compounds, as well as
2 combinations and mixtures of these and similar compounds that should be known to one
3 of skill in the art.

4 An illustrative primary emulsifier should be present in sufficient concentration to
5 stabilize the invert emulsion and preferably is selected from compounds including fatty
6 acids, soaps of fatty acids, amidoamines, polyamides, polyamines, oleate esters, such as
7 sorbitan monoleate, sorbitan dioleate, imidazoline derivatives or alcohol derivatives and
8 combinations or derivatives of the above. Blends of these materials as well as other
9 emulsifiers can be used for this application, as well as combinations and mixtures of these
10 and similar compounds that should be known to one of skill in the art. In one illustrative
11 embodiment a weighting agent or a bridging agent are optionally included in the drilling
12 fluid and in such instances the weighting agent or bridging agent is selected from galena,
13 hematite, magnetite, iron oxides, ilmenite, barite, siderite, celestite, dolomite, calcite
14 as well as combinations and mixtures of these and similar compounds that should be
15 known to one of skill in the art. As previously noted, the illustrative fluids may also
16 include conventional components of invert emulsion drilling muds, including, but not
17 limited to: fluid loss control agents, alkali reserve materials, and other conventional invert
18 emulsion drilling fluid components that should be well known to one of skill in the art.

19 Another illustrative embodiment of the disclosed subject matter includes a drilling
20 fluid that includes: an oleaginous fluid, which forms the continuous phase of the drilling
21 fluid; a non-oleaginous fluid, which forms the discontinuous phase of the drilling fluid; a
22 primary emulsifier that is in sufficient concentration to stabilize the invert emulsion; an
23 organophilic clay; and a rheology modifier. The rheology modifier that is used in the
24 illustrative embodiment may be a poly-carboxylic fatty acids, noted above. In an
25 alternative illustrative embodiment, the rheology modifier is a poly-amide as noted above.
26 As previously noted above, the oleaginous fluid component of the present illustrative
27 embodiment is from about 30% to about 100% by volume of the drilling fluid and is
28 composed of a material selected from diesel oil, mineral oil, synthetic oil, esters, ethers,
29 acetals, di-alkylcarbonates, olefins, as well as combinations and mixtures of these and
30 similar compounds that should be known to one of skill in the art.

1 Similarly, the non-oleaginous fluid utilized in the illustrative embodiment is from about
2 1% to about 70% by volume of said drilling fluid and is selected from fresh water, sea
3 water, a brine containing organic or inorganic dissolved salts, a liquid containing water-
4 miscible organic compounds, as well as combinations and mixtures of these and similar
5 compounds that should be known to one of skill in the art. The illustrative fluids may
6 also include conventional components of invert emulsion drilling muds, including, but
7 not limited to: weighting or bridging agents, fluid loss control agents, alkali reserve
8 materials, and other conventional invert emulsion drilling fluid components that should
9 be well known to one of skill in the art. When a weighting agent or bridging agent is
10 included, it may be selected from galena, hematite, magnetite, iron oxides, illmenite,
11 barite, siderite, celestite, dolomite, calcite as well as combinations and mixtures of these
12 and similar compounds that should be known to one of skill in the art.

13 One of skill in the art should also understand and appreciate that the claimed
14 subject matter includes the use of the fluids disclosed herein during the drilling of a
15 subterranean well.

16 These and other features are more fully set forth in the following description of
17 preferred or illustrative embodiments of the disclosed and claimed subject matter.

18

19 DESCRIPTION OF ILLUSTRATIVE EMBODIMENTS

20 The present disclosure is generally directed to an oil base well bore fluid that is
21 useful in the formulation of drilling, completing and working over of subterranean wells,
22 preferably oil and gas wells. The fluids may also be used as packing fluids, fracturing
23 fluids and other similar well bore uses in which flat rheology properties are desired. The
24 usefulness of the well bore fluids and invert emulsion fluids disclosed in this document
25 should be known to one of skill in the art as is noted in the book COMPOSITION AND
26 PROPERTIES OF DRILLING AND COMPLETION FLUIDS, 5th Edition, H.C.H.
27 Darley and George R. Gray, Gulf Publishing Company, 1988, the contents of which are
28 hereby incorporated herein by reference.

1 In one embodiment of the disclosed subject matter, a well bore fluid is formulated
2 to include an oleaginous fluid, a non-oleaginous fluid, a primary emulsifier, and a
3 rheology modifier. Each of these components is disclosed in greater detailed below.

4 An oleaginous fluid is a liquid and more preferably is a natural or synthetic oil and
5 more preferably the oleaginous fluid is selected from the group including diesel oil;
6 mineral oil; a synthetic oil, such as polyolefins, polydiorganosiloxanes, siloxanes or
7 organosiloxanes; and mixtures thereof. The concentration of the oleaginous fluid should
8 be sufficient so that an invert emulsion forms and may be less than about 99% by volume
9 of the invert emulsion. In one embodiment the amount of oleaginous fluid is from about
10 30% to about 95% by volume and more preferably about 40% to about 90% by volume of
11 the invert emulsion fluid. The oleaginous fluid in one embodiment may include a
12 mixture of internal olefin and alpha olefins. As is disclosed in a co-pending patent
13 application entitled "ENVIRONMENTALLY FRIENDLY OLEFIN MIXTURE DRILLING
14 FLUIDS", a combination of internal and alpha olefins can be used to create a drilling fluid
15 having a balance of desirable properties such as toxicity and biodegradability.
16 Specifically, in one illustrative embodiment a mixture of a C₁₆₋₁₈ internal olefin; a C₁₅₋₁₈
17 internal olefin; a C₁₅₋₁₆ internal olefin and a C₁₆ alpha olefin is made with a weight ratio
18 of 5/2/1.5/1.5 respectively. This results in an oleaginous fluid having a balance of
19 toxicity and biodegradability properties.

20 The non-oleaginous fluid used in the formulation of the invert emulsion fluid is a
21 liquid and preferably is an aqueous liquid. More preferably, the non-oleaginous liquid
22 may be selected from the group including fresh water, sea water, a brine containing
23 organic and/or inorganic dissolved salts, liquids containing water-miscible organic
24 compounds, combinations of these and similar compounds used in the formulation of
25 invert emulsions. The amount of the non-oleaginous fluid is typically less than the
26 theoretical maximum limit for forming an invert emulsion. Thus in one illustrative
27 embodiment the amount of non-oleaginous fluid is less than about 70% by volume and
28 preferably from about 1% to about 70% by volume. In another illustrative embodiment,
29 the non-oleaginous fluid is preferably from about 5% to about 60% by volume of the
30 invert emulsion fluid.

1 The primary emulsifier, utilized in the formulation of a drilling fluid in
2 accordance with the teachings of the present disclosure, should be selected so as to form a
3 useful and stable invert emulsion suitable for rotary drilling. The primary emulsifier
4 should be present in a concentration sufficient to for a stable invert emulsion that is useful
5 for rotary drilling. In one illustrative embodiment, the primary emulsifier is selected from
6 The emulsifiers that have demonstrated utility in the emulsions of this invention are fatty
7 acids, soaps of fatty acids, amidoamines, polyamides, polyamines, oleate esters, such as
8 sorbitan monoleate, sorbitan dioleate, imidazoline derivatives or alcohol derivatives and
9 combinations or derivatives of the above. Blends of these materials as well as other
10 emulsifiers can be used for this application. Other surfactant compounds may be used in
11 conjunction with the primary emulsifier utilized herein. In such cases it is important
12 however that the quantity and nature of these supplemental surfactants should not
13 interfere in the ability and properties given the invert emulsion fluid by the rheology
14 modifying agent to act as described herein.

15 The rheology modifier of the present disclosure is utilized to reduce the increase
16 in viscosity, i.e. flatten the rheological characteristics, of the drilling fluid over a
17 temperature range from about 40 °F to about 150 °F). In one illustrative embodiment, the
18 rheology modifier is a poly-carboxylic fatty acid. More preferably the poly-carboxylic
19 fatty acid is trimeric and therefore at least three carboxyl groups in the molecule, and
20 more preferably the trimeric poly-carboxylic acid is derived from tall oil or other similar
21 unsaturated long chain carboxylic acids (i.e. fatty acids) having from 12 to 22 carbons. A
22 particularly preferred embodiment is commercially available from M-I, of Houston TX as
23 EMI-755. It should be noted that the poly-carboxylic fatty acids utilized in the present
24 invention may include a dimer poly-carboxylic C₁₂ to C₂₂ fatty acid, trimer poly-
25 carboxylic C₁₂ to C₂₂ fatty acid, tetramer poly-carboxylic C₁₂ to C₂₂ fatty acid, mixtures of
26 these acids.

27 In another illustrative embodiment of the present invention, the rheology modifier
28 is a proprietary polyamide based rheology modifier based on a mixture of amides and
29 amines commercially available from M-I of Houston TX as EMI-756. When the
30 rheology modifier is a polyamide, the polyamide is preferably the condensation reaction

1 product of a C₁₂-C₂₂ fatty acid and a polyamine selected from the group consisting of
2 diethylenetriamine, triethylenetetramine; and pentaethylenetetramine. Generally the
3 condensation product is based on one equivalent of fatty acid for each equivalent of
4 amine present in the amine starting material.

5 The concentration of the rheology modifier should be sufficient to achieve the
6 results of the present invention. In one illustrative embodiment in which the rheology
7 modifier is a trimeric poly-carboxylic acid of tall oil, the concentration of turmeric acid
8 present in the drilling fluid may range from 0.1 to 5 pounds per barrel of drilling fluid and
9 more preferably is from about 0.5 to 2 pounds per barrel of fluid. In another illustrative
10 embodiment, the polyamide has a concentration greater than 0.1 and up to 5.0 pounds per
11 barrel.

12 Although not wishing to be bound by any specific theory of action, it is believed
13 that the relatively flat rheology profiles achieved by the present invention are the result of
14 the interaction of the rheology modifier with the fine solids, such as organophilic clays
15 and low-gravity solids present in the drilling fluid. It is believed that the interaction is
16 somewhat temperature motivated in such a way that the enhancement is greater at higher
17 temperatures and weaker at lower temperatures. One theory is that the change in
18 temperature causes a change in the molecular conformation of the rheology modifier such
19 that at higher temperatures more molecular interactions and thus higher viscosity than is
20 observed at lower temperatures. Alternatively, it is speculated that absorption /
21 desorption of the rheology modifier onto the surfaces of the solids present in the fluid is
22 related to the viscosity properties observed. Regardless of the mode of action, it has been
23 found that the addition of the rheology modifiers, as disclosed herein, to drilling fluids
24 results in the viscosity properties observed and disclosed below.

25 The disclosed drilling fluids are especially useful in the drilling, completion and
26 working over of subterranean oil and gas wells. In particular the fluids are useful in
27 formulating drilling muds and completion fluids for use in high deviation wells, and long
28 reach wells. Such muds and fluids are especially useful in the drilling of horizontal wells
29 into hydrocarbon bearing formations.

1 The method used in preparing the drilling fluids currently disclosed is not critical.
2 Conventional methods can be used to prepare the drilling fluids of the present invention
3 in a manner analogous to those normally used, to prepare conventional oil-based drilling
4 fluids. In one representative procedure, a desired quantity of oleaginous fluid such as a
5 base oil and a suitable amount of the primary emulsifier are mixed together followed by
6 the rheology modifying agent and the remaining components are added with continuous
7 mixing. An invert emulsion based on this fluid may be formed by vigorously agitating,
8 mixing or shearing the oleaginous fluid with a non-oleaginous fluid.

9 The fluids of the present invention may further contain additional components
10 depending upon the end use of the invert emulsion so long as they do not interfere with
11 the functionality of the rheology modifying agents described herein. For example, alkali
12 reserve, wetting agents, organophillic clays, viscosifiers, weighting agents, bridging
13 agents and fluid loss control agents may be added to the fluid compositions of this
14 invention for additional functional properties. The addition of such agents should be well
15 known to one of skill in the art of formulating drilling fluids and muds.

16 It is conventional in many invert emulsions to include an alkali reserve so that
17 the overall fluid formulation is basic (i.e. pH greater than 7). Typically this is in the
18 form of lime or alternatively mixtures of alkali and alkaline earth oxides and
19 hydroxides. One of skill in the art should understand and appreciate that the lime
20 content of a drilling fluid will vary depending upon the operations being undertaken
21 and the formations being drilled. Further it should be appreciated that the lime
22 content, also known as alkalinity or alkaline reserve is a property that is typically
23 measured in accordance with the applicable API standards which utilize methods that
24 should be well know to one of skill in the art of mud formulation.

25 Wetting agents that may be suitable for use include, crude tall oil, oxidized
26 crude tall oil, organic phosphate esters, modified imidazolines and amidoamines, alkyl
27 aromatic sulfates and sulfonates, and the like, and combinations or derivatives of these.
28 Versawet® and Versawet®NS are examples of commercially available wetting agents
29 manufactured and distributed by M-I L.L.C. that may be used in the disclosed drilling
30 fluids. Silwet L-77, L-7001, L7605 and L-7622 are examples of commercially

1 available surfactants and wetting agents manufactured and distributed by Union Carbide
2 Chemical Company Inc.

3 Organophilic clays, normally amine treated clays, may be useful as viscosifiers in
4 the fluid compositions of the disclosed subject matter. The amount of organophilic clay
5 used in the composition should be minimized to avoid an adverse effect upon the
6 rheological properties of the present inventive drilling fluids. However, normally about
7 0.1% to 6% by weight range are sufficient for most applications. VG-69 and VG-PLUS
8 are organo-clay materials distributed by M-I L.L.C., and Versa-HRP is a polyamide resin
9 material manufactured and distributed by M-I L.L.C., that may be used in the claimed
10 drilling fluids.

11 Weighting agents or density materials suitable for use in the described drilling
12 fluids include galena, hematite, magnetite, iron oxides, ilmenite, barite, siderite, celestite,
13 dolomite, calcite, and the like. The quantity of such material added, if any, depends upon
14 the desired density of the final composition. Typically, weight material is added to result
15 in a drilling fluid density of up to about 24 pounds per gallon. The weight material is
16 preferably added up to 21 pounds per gallon and most preferably up to 19.5 pounds per
17 gallon.

18 Fluid loss control agents typically act by coating the walls of the borehole as the
19 well is being drilled. Suitable fluid loss control agents which may find utility in this
20 invention include modified lignites, asphaltic compounds, gilsonite, organophilic
21 humates prepared by reacting humic acid with amides or polyalkylene polyamines, and
22 other non-toxic fluid loss additives. Typically, fluid loss control agents are added in
23 amounts less than about 10% and preferably less than about 5% by weight of the fluid.

24 The following examples are included to demonstrate preferred embodiments of
25 the claimed subject matter. It should be appreciated by those of skill in the art that the
26 techniques and compositions disclosed in the examples which follow represent
27 techniques discovered by the inventors to function well and thus can be considered to
28 constitute preferred modes of practice. However, those of skill in the art should, in light
29 of the present disclosure, appreciate that many changes can be made in the specific

1 embodiments which are disclosed and still obtain a like or similar result without
2 departing from the scope of the claimed subject matter.

3 General Information Relevant to the Examples

4 These tests were conducted in accordance with the procedures in API Bulletin RP
5 13B-2, 1990. The following abbreviations are sometimes used in describing the results of
6 experimentation.

7 “PV” is plastic viscosity, which is one variable used in the calculation of viscosity
8 characteristics of a drilling fluid, measured in centipoise (cp) units.

9 “YP” is yield point, which is another variable used in the calculation of viscosity
10 characteristics of drilling fluids, measured in pounds per 100 square feet (lb/100 ft²).

11 “AV” is apparent viscosity, which is another variable, used in the calculation of
12 viscosity characteristic of drilling fluid, measured in centipoise (cp) units.

13 “GELS” is a measure of the suspending characteristics, or the thixotropic
14 properties of a drilling fluid, measured in pounds per 100 square feet (lb/100 ft²).

15 “API F.L.” is the term used for API filtrate loss in milliliters (ml).

16 “HTHP” is the term used for high-temperature high-pressure fluid loss, measured
17 in milliliters (ml) according to API bulletin RP 13 B-2, 1990.

18 The components of the claimed drilling fluids include oleaginous fluid, a non-
19 oleaginous fluid, an emulsifier package and a rheology modifier. Other chemicals used to
20 make-up the system are basically the same as those typically used in formulating
21 conventional invert drilling fluid systems. A description of individual components is
22 given below:

23 **EMI 595** - is the main emulsifier is an amidoamine and has a chemistry and
24 structure designed to minimize interactions with formation and drill solids. The
25 recommended concentration is 7-8 ppb, but it can be used in concentrations varying from
26 5 to 10 ppb. However, higher concentrations may result in a minor thinning effect on
27 rheology. The product is commercially available from Champion Chemicals and/or M-I
28 LLC.

29 **EMI-157** - is an oleic acid based wetting agent and is used as a secondary
30 emulsifier. The recommended concentration is 1-2 ppb. Concentrations over 2 ppb

1 should be pilot tested for increase in rheology and sheen character of the system. The
2 product is commercially available from M-I LLC.

3 **EMI-755** - is a trimer acid based rheology modifier. The flat rheology profile is
4 generated using this rheology modifier. The compound is believed to enhance low-end
5 rheology and yield point by interacting with fine solids such as organo clay and low-
6 gravity solids. The interaction appears to be temperature dependent in such a way that the
7 enhancement is greater at high temperature and weaker at low temperatures. It is believed
8 that the interaction may be due to a change of the conformation of the trimer acid with
9 temperature, such as that it may open up more at high temperatures thus generating more
10 viscosity than at low temperatures; or due to adsorption/desorption from the surfaces of
11 solids. The enhancement in low-end rheology and yield point can be affected by the
12 amount of organo clay and fine low-gravity solids in the system. A larger amount of
13 organo clays or fine low-gravity solids tends to cause a greater increase in these properties
14 and a flatter profile. When using this compound as the rheology modifier, it is best to
15 keep the low-gravity solids content in the 2-4% range. The recommended concentration is
16 about 0.1 up to 5.0 ppb and preferably 1-2 ppb.

17 **EMI-756** - is a polyamide based viscosifier and rheology modifier that can be
18 used to increase viscosity and improve sag control of the flat rheology system when
19 needed. This viscosifier is chemically different from the trimer acid based rheology
20 modifier, thus it interacts with solids differently. This polymer can generate high
21 viscosity when added to a system containing a moderate to large amount of low-gravity
22 solids, therefore pilot test is highly recommended before its addition. The recommended
23 concentration is about 0.1 up to 5.0 ppb and preferably 0.25 - 1.0 ppb.

24 **EMI-711** - is a thinning agent that can be used to reduce overall rheology of the
25 system without significantly changing the flat rheology profile. Because of its potency,
26 EMI-711 should be pilot tested before adding to the active system. Typically, a treatment
27 level of 0.25 ppb or less is a good starting point.

28 **VG Plus** - This organo clay is used at a minimal amount to provide some body
29 and viscosity for proper barite suspension and gel strength. Typically, 1-2 ppb of this
30 organo clay should be sufficient for this purpose. For high temperature applications or for

barite sag controls, other organo clays, such as Bentone 42 and VG Supreme, may be used to replace VG Plus. VG Plus may be added in the form of pre-mix during drilling to maintain the flat rheology profile. VG-Plus, is commercially available from M-I LLC.

EcoTrol - is a fluid loss control agent. Typical concentration required is 0.5 - 1.0 ppb for the flat rheology system. Temperature and shear tend to facilitate the dispersing and solubilization of this product in the system. EcoTrol is commercially available from M-I LLC.

Example 1: Base Mud Formulation and Property

The composition and mixing of three flat rheology fluids with mud weight ranging from 11.0 ppg to 15.6 ppg are shown in Table 1 as an illustration. Mixing of the disclosed drilling fluid formulations is not significantly different from the processed for mixing other invert emulsion fluids. Such processes should be well known to one of skill in the art of drilling fluid formulation. However, because the stabilizing effects from shearing, temperature, and drill solids are not available at mixing plant, the initial properties of a freshly made invert emulsion fluid can be quite different from a used field mud. To ensure that the initial properties of the EMS 4000 would approach its stabilized properties the emulsion stability of the fluid also need to be monitored often to ensure sufficient shearing has been applied. To maintain a low and flat rheology profile the S/W ratio, amounts of organo clay and rheology modifier were adjusted slightly according to the mud weight.

Table 1. Composition of flat rheology system of different synthetic/water ratio and mud weight. The recommended order of mixing is the same as the order the products are listed.

	11.0 ppg	13.0 ppg	15.6 ppg
S/W Ratio	70/30	75/25	80/20
1. Base (IO/AO Blend), bbls	0.5714	0.5600	0.5278
2. VG Plus, ppb	2	1	0.75
3. Lime, ppb	3	3	3
4. EMI-595, ppb	7	7	7
5. MI-157, ppb	2	1.5	2
6. CaCl ₂ brine, bbls	0.2571 (20%)	0.2023 (25%)	0.1428 (25%)

7. EcoTrol, ppb	0.5	0.5	0.5
8. Barite, ppb	185	290	442
9. EMI-755, ppb	2	2.5	1.7

The rheological and HTHP fluid loss properties of the above flat rheology fluids after hot rollings are shown in Table 2. To demonstrate the flat rheology profile, the rheology of the fluids were measured using Fann 35A viscometer at 40°F, 70°F & 100°F, or 40°F, 100°F & 150°F after hot rolling at 100°F or 150°F for 16 hours, respectively. Since the 11.0 ppg fluid was hot rolled only at 100°F, the measurement at 150°F was considered irrelevant.

Table 2. Properties of typical flat rheology fluids after hot rolling (AHR) at temperatures indicated.

	11.0 ppg, AHR at 100°F			13.00 ppg, AHR at 150°F			15.6 ppg AHR at 150°F		
<i>Rheology at</i>	<i>40 °F</i>	<i>70 °F</i>	<i>100 °F</i>	<i>40 °F</i>	<i>100 °F</i>	<i>150 °F</i>	<i>40 °F</i>	<i>100 °F</i>	<i>150 °F</i>
600	104	73	60	106	62	45	128	65	50
300	59	41	35	62	38	30	72	37	31

ES	290			670			520		
HTHP FL	5.6 at 200°F			5.2 at 250°F			14.2 at 250°F		

Upon review of the above illustrative data, one of skill in the art should notice the similar rheology displayed despite different mud weights. Further it should be noticed that while there was a slight change in rheology of the mud formulation the change is less substantial than a comparable mud without the benefit of the rheology modifiers disclosed herein.

Example 2: Effects of Content of Organo Clay and Rheology Modifier

Because the flat rheological properties were produced from the interaction of the rheology modifier and organo clays, it is necessary to investigate the effects of rheology modifier as a function of organo clay contents. A review of the resulting data illustrates the change of rheological properties as a function of the content of organo clay (C) and rheology modifier (RM). To facilitate a direct comparison, a graphical comparison is useful so long as the vertical scale is adjusted to the same in all three plots. One of skill in the art should notice in the above illustrative data that a trend of increasing properties with increasing content of organo clay and rheology modifier. Based on the initial data, it was concluded that the most effective system formulation would be one that contains 1-2 ppb of organo clays, 5-8 ppb of emulsifier, 1-2 ppb of wetting agent, 1-2 ppb of rheology modifier, and 0.5-1 ppb of fluid loss control agent.

Example 3: Effects of Solids, Seawater, and Cement Contamination

Using the 13.0 ppg fluid as an example, the retention of the flat rheological property of the system in the event of drill solids, seawater, and cement contamination is illustrated in Table 3. Because the system is not 100% inert to contamination, some changes in rheological properties did occur after each contaminant was added, when compared with the contaminant-free base mud. One noticeable change is the increase in 10-min gel strength after solids contamination. This increase was attributed to the interaction of the rheology modifier and the low gravity solids.

Table 3. Effects of solids, seawater, cement contamination on a 13 ppg flat rheology mud. Notice the flat rheology profile is retained after the contamination, despite some noticeable changes in rheology.

	13.0 ppg Base Mud			Base + 35 ppb OCMA Clay			Base + 10% Seawater			Base + 10 ppb Class G Cement

Upon review of the above illustrative data, one of skill in the art should understand and appreciate that in a comparison of the 6-rpm reading, YP, and 10' Gel strength of OCMA Clay, seawater, and cement contaminated fluids with base mud, the original flat rheology property is more or less retained after the contamination.

Similar contamination tests also have been conducted using the 11.0 ppg mud formulation. Because of the higher organo-clay in the formulation, the solids contamination resulted in a greater increase in rheology. However, when the system was properly diluted with a premix to maintain the original mud weight, the rheology dropped back to the desired range. Illustrative rheological changes of the 11.0 ppg system before and after the solids contamination and dilution are given in Table 4.

Table 4. Rheological properties of the 11.0 ppg system after solids contamination and 10% dilution with an unweighted base fluid having an 80/20 S/W ratio.

* Premix: 80/20 base containing 1 ppb VG Plus, 3 ppb Lime, 7 ppb EMI-595, 2 ppb MI-157 and 1 ppb EMI-755

One of skill in the art should appreciate that the above illustrative test results indicate that for the field trial the system properties can be maintained with proper dilution. Treatment with a small amount of thinner can be used to further reduce the rheology.

Example 4: Addition of Lime

While testing the 11 ppg drilling fluid formulated as disclosed herein it was noticed that the flat rheology profile is more apparent after heat aging than before heat aging, indicating that time and temperature could be important factors that can stabilize the flat properties. For most applications where bottom hole temperature is above 150°F, the fluid system should stabilize after a few days of drilling. However, in wells with a low bottom hole temperature and short section length, the flat rheological property may not get fully developed and stabilized. Thus, it may be necessary to achieve the flat rheology disclosed herein with a freshly made fluid. In the process of trying to stabilize the flat rheological property of freshly made fluid, it was noticed that addition of lime may help to achieve this goal.

Table 5 shows the properties of two 11.0 ppg fluids (A and B) that were mixed under similar conditions with similar mud composition. The only difference is that the second fluid (B) had one extra pound of Lime added at the end of the mixing.

Table 5. Adding one extra pound of Lime at the end of mixing tends to stabilize the flat rheology profile before heat aging. Both A and B fluids have same mud composition except Lime content.

	11ppg-A			11-ppg A, AHR			11 ppg-B			11 ppg-B, AHR		
<i>Rheology at</i>	40°F	70°F	100°F	40°F	70°F	100°F	40°F	70°F	100°F	40°F	70°F	100°F
600	121	98	76	104	73	60	98	78	63	107	73	60
300	82	69	52	59	41	35	57	47	42	60	41	35

3	18	16	12	9	9	12	12	15	15	9	8	11
PV	39	29	24	45	32	25	41	31	21	47	32	25
YP	43	40	28	14	9	10	16	16	21	13	9	10
10" Gels	18	16	14	14	15	15	18	19	18	13	15	15
10" Gels	21	20	17	22	21	22	25	25	25	23	23	22
ES	280			290			310			370		

Upon review one of skill in the art should appreciate that the extra pound of lime added at the end of the mixing, the second fluid displayed the desired flat rheology profile before hot rolling. However, after heat aging at 100°F, both fluids showed almost identical rheology, indicating that the effect of adding lime is somehow affected by the heat aging process.

It is believed that treatment with lime can be used to equip the freshly made fluid with the flat rheology property when such a property is needed at the mixing plant. It is also believed that cement probably would have pretty much the same effect on the system, when a freshly made fluid is used to drill cement. Thus if the freshly made mud is planned to drill cement, such treatment may not be needed at the mixing plant.

Example 5: Effects of Thinner and Wetting Agent

Although the flat rheology system is designed to run most efficiently with a low content of drilled solids (2-4%), often time it may be necessary to treat the system with a thinner or wetting agent to reduce the overall viscosity and gel strength of the system, such as before running casing. Data illustrative of the effects of different thinners and wetting agents on the rheology of a 13 ppg EMS 4000 system loaded with 50 ppb of OCMA Clay have been evaluated and shows the effects of different thinners and wetting agents on the flat rheology property of a 13 ppg EMS 4000. The base mud contained 50 ppb of OCMA Clay as drill solids. The most effective thinners are NovaThin and EMI-711. Wetting agents such as MI-157 and NovaWet actually caused some increases in rheology. VersaWet showed least impact on the rheology.

Based on the test results, one of skill in the art should appreciate that NovaThin and EMI-711 provided very good thinning effects, whereas wetting agents showed some

1 increases in rheology. Because of the powerful thinning effect of EMI-711, pilot test
2 should be conducted before addition of the product is carried out on a rig.

4 **Example 6: Barite Sag**

5 For extended reach applications, barite sag can cause various potential problems.
6 A 13.0 ppg flat rheology system has been tested for barite sag control using a sag flow
7 loop tester.

8 About 2.8 gallons of the test mud is circulated in the flow loop consisting of a
9 plastic test tube (2" ID x 6' long), a circulating pump, and a densitometer. The plastic
10 tube can be adjusted at angles varying from vertical (0-degree) to horizontal (90-degree).
11 Inside the plastic tube, a steel rod is used to simulate drill string and can be rotated at
12 speeds varying from 0 to 225 rpm. For barite sag evaluation, the test normally is
13 conducted at 60-degree inclination with varying pump rates (from 25 to 185 fpm annular
14 velocity) and pipe rotations (from 0 to 225 rpm). Changes of mud weight due to
15 sagging/settling of barite or other weighting agent in the test tube are determined by the
16 densitometer under circulating conditions. After the sag test, the mud weight data were
17 corrected to a constant temperature of 120°F for comparison.

18 Upon review of the resulting data one of skill in the art should appreciate that the
19 sag curves are plots of mud weight changes (mostly mud weight drop) observed during
20 the 200-min test. The base mud run without OCMA Clay, which is not shown, had a
21 greater mud weight drop due to its relatively low rheology profile. After the addition of
22 OCMA Clay, however, the barite sag was significantly minimized due to an increase in
23 rheology. Some stabilizing effect is also indicated by the leveled-off curve.

24 The system was treated with 1.0 ppb of EMI-756 and re-tested. Upon review one
25 of skill in the art should notice that a further reduction in barite sag was observed with the
26 treatment, which only caused 15-20% increase in rheology.

27 In view of the above disclosure, one of ordinary skill in the art should understand
28 and appreciate that one illustrative embodiment of the claimed subject matter includes a
29 drilling fluid formulated to include: an oleaginous fluid that forms the continuous phase;
30 a non-oleaginous fluid that forms the discontinuous phase, a primary emulsifier which is

1 in sufficient concentration to stabilize the invert emulsion; and a rheology modifier
2 selected to substantially achieve the result disclosed above. It is preferred that the
3 rheology modifier is a concentration sufficient to achieve the result described above and
4 is selected from poly-carboxylic fatty acids and poly-amides. In one preferred illustrative
5 embodiment, the rheology modifier is selected from the group consisting of a dimer poly-
6 carboxylic C₁₂ to C₂₂ fatty acid, trimer poly-carboxylic C₁₂ to C₂₂ fatty acid, tetramer
7 poly-carboxylic C₁₂ to C₂₂ fatty acid, mixtures of these acids, and polyamide wherein the
8 polyamide is the condensation reaction product of a C₁₂-C₂₂ fatty acid and a polyamine
9 selected from the group consisting of diethylenetriamine, triethylenetetramine; and
10 pentaethylenetetramine. As noted above, the oleaginous fluid utilized in the present
11 illustrative embodiment forms the continuous phase and is about 30% to about 100% by
12 volume of the drilling fluid and preferably is selected from diesel oil, mineral oil,
13 synthetic oil, esters, ethers, acetals, di-alkylcarbonates, olefins, as well as combinations
14 and mixtures of these and similar compounds that should be known to one of skill in the
15 art. In another illustrative embodiment, the non-oleaginous fluid composes the
16 discontinuous phase and is about 1% to about 70% by volume of said drilling fluid with
17 preferred non-oleaginous fluid being selected from fresh water, sea water, a brine
18 containing organic or inorganic dissolved salts, a liquid containing water-miscible organic
19 compounds, as well as combinations and mixtures of these and similar compounds that
20 should be known to one of skill in the art.

21 An illustrative primary emulsifier should be present in sufficient concentration to
22 stabilize the invert emulsion and preferably is selected from compounds that should be
23 known to one of skill in the art. In one illustrative embodiment a weighting agent or a
24 bridging agent are optionally included in the drilling fluid and in such instances the
25 weighting agent or bridging agent is selected from galena, hematite, magnetite, iron
26 oxides, illmenite, barite, siderite, celestite, dolomite, calcite as well as combinations and
27 mixtures of these and similar compounds that should be known to one of skill in the art.
28 As previously noted, the illustrative fluids may also include conventional components of
29 invert emulsion drilling muds, including, but not limited to: fluid loss control agents,

1 alkali reserve materials, and other conventional invert emulsion drilling fluid components
2 that should be well known to one of skill in the art.

3 Another illustrative embodiment of the disclosed subject matter includes a drilling
4 fluid that includes: an oleaginous fluid, which forms the continuous phase of the drilling
5 fluid; a non-oleaginous fluid, which forms the discontinuous phase of the drilling fluid; a
6 primary emulsifier that is in sufficient concentration to stabilize the invert emulsion; an
7 organophilic clay; and a rheology modifier. The rheology modifier that is used in the
8 illustrative embodiment may be selected from the group consisting of a dimer poly-
9 carboxylic C₁₂ to C₂₂ fatty acid, trimer poly-carboxylic C₁₂ to C₂₂ fatty acid, tetramer
10 poly-carboxylic C₁₂ to C₂₂ fatty acid, mixtures of these acids, and polyamide wherein the
11 polyamide is the condensation reaction product of a C₁₂-C₂₂ fatty acid and a polyamine
12 selected from the group consisting of diethylenetriamine, triethylenetetramine; and
13 pentaethylenetetramine. When a polyamide is used in one illustrative embodiment the
14 polyamide is the condensation product of one mole of diethylenetriamine and three moles
15 of C₁₂-C₂₂ fatty acid. As previously noted above, the oleaginous fluid component of the
16 present illustrative embodiment is from about 30% to about 100% by volume of the
17 drilling fluid and is composed of a material selected from diesel oil, mineral oil, synthetic
18 oil, esters, ethers, acetals, di-alkylcarbonates, olefins, as well as combinations and
19 mixtures of these and similar compounds that should be known to one of skill in the art.
20 Similarly, the non-oleaginous fluid utilized in the illustrative embodiment is from about
21 1% to about 70% by volume of said drilling fluid and is selected from fresh water, sea
22 water, a brine containing organic or inorganic dissolved salts, a liquid containing water-
23 miscible organic compounds, as well as combinations and mixtures of these and similar
24 compounds that should be known to one of skill in the art. The illustrative fluids may
25 also include conventional components of invert emulsion drilling muds, including, but
26 not limited to: weighting or bridging agents, fluid loss control agents, alkali reserve
27 materials, and other conventional invert emulsion drilling fluid components that should
28 be well known to one of skill in the art. When a weighting agent or bridging agent is
29 included, it may be selected from galena, hematite, magnetite, iron oxides, illmenite,

1 barite, siderite, celestite, dolomite, calcite as well as combinations and mixtures of these
2 and similar compounds that should be known to one of skill in the art.

3 One of skill in the art should also understand and appreciate that the claimed
4 subject matter includes the use of the fluids disclosed herein during the drilling of a
5 subterranean well. In one such illustrative embodiment of a method of rotary drilling a
6 subterranean well using a drilling fluid, the improvement includes using a drilling fluid
7 that includes: an oleaginous fluid, a non-oleaginous fluid, a primary emulsifier, an
8 organophillic clay; and a rheology modifier. The oleaginous fluid forms the continuous
9 phase and the non-oleaginous fluid forms the discontinuous phase of the drilling fluid.
10 The oleaginous fluid is from about 30% to about 100% by volume of the drilling fluid
11 and are composed of a material selected from diesel oil, mineral oil, synthetic oil, esters,
12 ethers, acetals, di-alkylcarbonates, olefins, as well as combinations and mixtures of these
13 and similar compounds that should be known to one of skill in the art. The non-
14 oleaginous fluid comprises from about 1% to about 70% by volume of the drilling fluid
15 and the non-oleaginous fluid is selected from fresh water, sea water, a brine containing
16 organic or inorganic dissolved salts, a liquid containing water-miscible organic
17 compounds, as well as combinations and mixtures of these and other fluids that should be
18 known to one of skill it the art. The primary emulsifier should be in sufficient
19 concentration to stabilize the invert emulsion and can be selected from combinations and
20 mixtures of these and other fluids that should be known to one of skill it the art. The flat
21 rheology characteristics of the fluid are substantially imparted by the inclusion of the
22 rheology modifier, which is selected from poly-carboxylic fatty acids and poly-amides. In
23 one illustrative embodiment, the poly-carboxylic fatty acid is a mixture of poly-carboxylic
24 acids added in sufficient concentration so that the trimeric poly-carboxylic fatty acid
25 concentration in the drilling fluid is greater than 0.1 pounds per barrel and is up to 5.0
26 pounds per barrel. Another illustrative embodiment utilizes, a poly-amide as the rheology
27 modifier which is the condensation product of one mole of diethylenetriamine and three
28 moles of C₁₂-C₂₂ fatty acid as well as combinations and mixtures of these and other
29 compounds that should be known to one of skill it the art. As previously noted, the
30 illustrative fluids may also include conventional components of invert emulsion drilling

1 muds, including, but not limited to: weighting or bridging agents, fluid loss control
2 agents, alkali reserve materials, and other conventional invert emulsion drilling fluid
3 components that should be well known to one of skill in the art.

4 While the apparatus, compositions and methods disclosed above have been
5 described in terms of preferred or illustrative embodiments, it will be apparent to those of
6 skill in the art that variations may be applied to the process described herein without
7 departing from the concept and scope of the claimed subject matter. All such similar
8 substitutes and modifications apparent to those skilled in the art are deemed to be within
9 the scope and concept of the subject matter as it is set out in the following claims.
10
